Field of the Invention The present invention relates to a method of sensing strain by extracting parameters of the strain-induced electrical potential from a model of the electrical potential. 2. Description of the Prior Art There are many cases in which it is desirable to measure strain which has been applied to a structure to an extremely small degree. For example, in the case of a rolling stock, it is desirable to detect strain with an accuracy of, for example, a degree of a few thousandth of 1%. It is considered that, in most cases of conventional measurement, a strain-induced strain tensor is obtained, from which strain vectors are obtained. In this case, for example, the calculation which will be explained subsequently is carried out using the strain vectors. The conventional strain measurement method to which the present invention is applied can be roughly divided into a non-contact method and a contact method. FIG. 1 is a conceptual diagram showing a conventional non-contact strain measurement method. Referring to FIG. 1, in the non-contact method, there is prepared a part of a structure 1 to be measured, such as a rolling stock, and a strain-detecting instrument 2 is attached on the outside of the structure. The strain-detecting instrument is required to have a function of converting strain vectors detected on the basis of the displacement caused by the strain into parameters of electrical potential difference. The strain-detecting instrument 2 has, as an essential part thereof, a strain-detecting unit 7 and a converter f678ea9f9e
